Overview

The Bézier patch is the surface extension of the Bézier curve. The definition of the patch follows directly the definition of the curve, with the primary differences being the use of an array of control points and the bivariate Bernstein Polynomials. The edge curves of the patch are Bézier curves and the “corner” control points are always on the curve.

In these notes we show that a patch can be treated as a continuous set of Bézier curves. That is, for any fixed parameter \( u_0 \) or \( v_0 \) we can define a Bézier curve that lies directly on the surface of the patch. This is a very valuable tool for calculations on the patch.

Calculating Bézier Curves on Bézier Patches

In the development of the Bézier patch, we have shown that the boundary curves of the patch are Bézier curves – that is, \( P(0, v) \) and \( P(1, v) \) are Bézier curves lying on the boundary of the patch.

If we examine the definition of a Bézier patch closely, and group factors appropriately,

\[
P(u, v) = \sum_{j=0}^{m} \left[ \sum_{i=0}^{n} P_{i,j} B_{i,n}(u) \right] B_{j,m}(v)
\]

we notice that portion of the equation inside the brackets is the representation of a Bézier curve – in fact there are \( m + 1 \) of these, one for each \( j \). If we fix \( u = u_0 \), we can use our Bézier curve evaluation scheme to generate a point \( Q_j = \sum_{i=0}^{n} P_{i,j} B_{i,n}(u_0) \) for each \( j = 0, 1, ..., m \). So, when \( u = u_0 \), the equation (1) reduces to

\[
P(u_0, v) = \sum_{j=0}^{m} Q_j B_{j,m}(v)
\]
which is just a Bézier curve lying on the patch. So the patch is made up of a continuous set of Bézier curves!

If we define $Q_j(u)$ to be the quantity

$$Q_j(u) = \sum_{i=0}^{n} P_{i,j} B_{i,n}(u)$$

(i.e. the value inside the brackets above) then we can see that

$$P(u, v) = \sum_{j=0}^{m} Q_j(u) B_{j,m}(v).$$

That is, the quantities $Q_j(u)$ form the control points of a Bézier curve – for each $u$ – thus $P(u, v)$ is just blending together a bunch of Bézier curves.

So, given $u = u_0$, we can calculate the quantities $Q_0(u_0), Q_1(u_0), ..., Q_m(u_0)$, giving $m$ control points to utilize for the curve

$$Q(v) = P(u_0, v) = \sum_{j=0}^{m} Q_j(u_0) B_{j,m}(v)$$

This curve lies completely on the patch – it is just $P(u_0, v)$ – and calculating $Q(v_0)$ gives us the point on the patch at $(u_0, v_0)$.

The following illustration shows the relationship between the $Q$s and the $P$s in the $4 \times 4$ case.

First the point $Q_0(u_0)$ is calculated as a point on the Bézier curve defined by the control points $P_{0,0}, P_{1,0}, P_{2,0}$ and $P_{3,0}$. 

2
next the point $Q_1(u_0)$ is calculated as a point on the Bézier curve defined by the control points $P_{0,1}$, $P_{1,1}$, $P_{2,1}$ and $P_{3,1}$. 
then the point $Q_2(u_0)$ is calculated as a point on the Bézier curve defined by the control points $P_{0,2}, P_{1,2}, P_{2,2}$ and $P_{3,2}$.

and finally, the point $Q_2(u_0)$ is calculated as a point on the Bézier curve defined by the control points $P_{0,3}, P_{1,3}, P_{2,3}$ and $P_{3,3}$.
The point \( P(u_0, v_0) \), on the patch, is calculated as a point on the Bézier curve defined by the control points \( Q_0(u_0), Q_1(u_0), Q_2(u_0) \) and \( Q_3(u_0) \),
So, we can calculate a point on the patch at \((u_0, v_0)\) by using five “Bézier curve calculations”.

---

**Reversing the Order of Things**

If we reverse the order of the sums in the defining equation and regroup, we find that

\[
P(u, v) = \sum_{i=0}^{m} \left[ \sum_{j=0}^{n} P_{i,j} B_{j,n}(v) \right] B_{i,m}(u)
\]

which implies, if we do the above construction again, that we can first fix \(v = v_0\), define control points \(Q_0(v_0), Q_1(v_0), ..., Q_n(v_0)\) and define the equation as

\[
P(u, v) = \sum_{i=0}^{m} Q_i(v_0) B_{i,m}(u)
\]

which is again a Bézier curve lying on the surface.

Thus, we can either do this procedure by fixing \(u\) first, or fixing \(v\) first, and we obtain the same result.

So, we have that the Bézier patch is a continuous set of Bézier curves, either in the \(u\) direction of the patch, or the \(v\) direction.

---

**Summary**

The Bézier patch is a direct extension of the Bézier curve to surfaces. The definition of the patch follows directly the definition of the curve, with the primary differences being the use of an array of control points and the bivariate Bernstein Polynomials. The patch can be treated as a continuous set of Bézier curves, and the calculations to find a point on the patch can be reduced to finding several points on curves using the Bézier curve methodology.

So there are no special calculation methods for Bézier patches, we just use the curve methods a few times to make things work on the patch. The calculations are parameter independent in that it does not matter whether we start with the \(u\) or \(v\) parameter.
